Formula 1

15 wherein n, m, X, Y, R<sub>1</sub>, R<sub>2</sub>, R<sub>3</sub>, R<sub>4</sub>, R<sub>5</sub> and R<sub>6</sub> are defined more fully below.

It has been found that PTPases plays a major role in the intracellular modulation and regulation of fundamental cellular signaling mechanisms involved in metabolism, growth, proliferation and differentiation (Hunter, *Phil. Trans. R. Soc. Lond. B* 353: 583-605 (1998); Chan *et al.*, *Annu. Rev. Immunol.* 12: 555-592 (1994); Zhang, *Curr. Top. Cell. Reg.* 35: 21-68 (1997); Matozaki and Kasuga, *Cell. Signal.* 8: 113-19 (1996); Flint *et al.*, *The EMBO J.* 12:1937-46 (1993); Fischer *et al.*, *Science* 253:401-6 (1991)). Overexpression or altered activity of tyrosine phosphatases can also contribute to the symptoms and progression of various diseases (Wiener, *et al.*, *J. Natl. cancer Inst.* 86:372-8 (1994); Hunter and Cooper, *Ann. Rev. Biochem.* 54:897-930 (1985)). Furthermore, there is increasing evidence which suggests that inhibition of these PTPases may help treat certain types of diseases such as diabetes type I and II, autoimmune disease, acute and chronic inflammation, osteoporosis and various forms of cancer.

## Background of the Invention

Protein phosphorylation is now well recognized as an important mechanism utilized by cells to transduce and regulate signals during different stages of cellular function (Hunter, *Phil.*

*Trans. R. Soc. Lond. B* 353: 583-605 (1998); Chan *et al.*, *Annu. Rev. Immunol.* 12: 555-592 (1994); Zhang, *Curr. Top. Cell. Reg.* 35: 21-68 (1997); Matozaki and Kasuga, *Cell. Signal.* 8: 113-19 (1996); Fischer *et al.*, *Science* 253:401-6 (1991); Flint *et al.*, *EMBO J.* 12:1937-46 (1993)). There are at least two major classes of phosphatases: (1) those that dephosphorylate proteins (or peptides) that contain a phosphate group(s) on a serine or threonine moiety (termed Ser/Thr phosphatases) and (2) those that remove a phosphate group(s) from the amino acid tyrosine (termed protein tyrosine phosphatases or PTPases or PTPs).

The PTPases are a family of enzymes that can be classified into two groups: a) intracellular or nontransmembrane PTPases and b) receptor-type or transmembrane PTPases.

**Intracellular PTPases:** Most known intracellular type PTPases contain a single conserved catalytic phosphatase domain consisting of 220-240 amino acid residues. The regions outside the PTPase domains are believed to play important roles in localizing the intracellular PTPases subcellularly (Mauro, L.J. and Dixon, J.E. *TIBS* 19: 151-155 (1994)). The first intracellular PTPase to be purified and characterized was **PTP1B**, which was isolated from human placenta (Tonks *et al.*, *J. Biol. Chem.* 263: 6722-6730 (1988)). Shortly after, PTP1B was cloned (Charbonneau *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 5252-5256 (1989); Chernoff *et al.*, *Proc. Natl. Acad. Sci. USA* 87: 2735-2789 (1989)). Other examples of intracellular PTPases include (1) T-cell PTPase/ TC-PTP (Cool *et al.* *Proc. Natl. Acad. Sci. USA* 86: 5257-5261 (1989)), (2) rat brain PTPase (Guan *et al.*, *Proc. Natl. Acad. Sci. USA* 87:1501-1502 (1990)), (3) neuronal phosphatase **STEP** (Lombroso *et al.*, *Proc. Natl. Acad. Sci. USA* 88: 7242-7246 (1991)), (4) ezrin-domain containing PTPases: **PTPMEG1** (Guet *et al.*, *Proc. Natl. Acad. Sci. USA* 88: 5867-57871 (1991)), **PTPH1** (Yang and Tonks, *Proc. Natl. Acad. Sci. USA* 88: 5949-5953 (1991)), **PTPD1** and **PTPD2** (Møller *et al.*, *Proc. Natl. Acad. Sci. USA* 91: 7477-7481 (1994)), **FAP-1/BAS** (Sato *et al.*, *Science* 268: 411-415 (1995); Banville *et al.*, *J. Biol. Chem.* 269: 22320-22327 (1994); Maekawa *et al.*, *FEBS Letters* 337: 200-206 (1994)), and SH2 domain containing PTPases: **PTP1C/SH-PTP1/SHP-1** (Plutzky *et al.*, *Proc. Natl. Acad. Sci. USA* 89: 1123-1127 (1992); Shen *et al.*, *Nature Lond.* 352: 736-739 (1991)) and **PTP1D/Syp/SH-PTP2/SHP-2** (Vogel *et al.*, *Science* 259: 1611-1614 (1993); Feng *et al.*, *Science* 259: 1607-1611 (1993); Bastein *et al.*, *Biochem. Biophys. Res. Comm.* 196: 124-133 (1993)).

**Receptor-type PTPases** consist of a) a putative ligand-binding extracellular domain, b) a transmembrane segment, and c) an intracellular catalytic region. The structures and sizes of the putative ligand-binding extracellular domains of receptor-type PTPases are quite divergent. In contrast, the intracellular catalytic regions of receptor-type

PTPases are very homologous to each other and to the intracellular PTPases. Most receptor-type PTPases have two tandemly duplicated catalytic PTPase domains.

The first receptor-type PTPases to be identified were (1) **CD45/LCA** (Ralph, S.J., *EMBO J.* 6: 1251-1257 (1987)) and (2) **LAR** (Streuli *et al.*, *J. Exp. Med.* 168: 1523-1530 (1988)) that were recognized to belong to this class of enzymes based on homology to PTP1B (Charbonneau *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 5252-5256 (1989)). CD45 is a family of high molecular weight glycoproteins and is one of the most abundant leukocyte cell surface glycoproteins and appears to be exclusively expressed upon cells of the hematopoietic system (Trowbridge and Thomas, *Ann. Rev. Immunol.* 12: 85-116 (1994)).

The identification of CD45 and LAR as members of the PTPase family was quickly followed by identification and cloning of several different members of the receptor-type PTPase group. Thus, 5 different PTPases, (3) **PTP $\alpha$** , (4) **PTP $\beta$** , (5) **PTP $\delta$** , (6) **PTP $\epsilon$** , and (7) **PTP $\zeta$** , were identified in one early study (Krueger *et al.*, *EMBO J.* 9: 3241-3252 (1990)). Other examples of receptor-type PTPases include (8) **PTP $\gamma$**  (Barnea *et al.*, *Mol. Cell. Biol.* 13: 1497-1506 (1995)) which, like **PTP $\zeta$**  (Krueger and Saito, *Proc. Natl. Acad. Sci. USA* 89: 7417-7421 (1992)) contains a carbonic anhydrase-like domain in the extracellular region, (9) **PTP $\mu$**  (Gebbink *et al.*, *FEBS Letters* 290: 123-130 (1991)), (10) **PTP $\kappa$**  (Jiang *et al.*, *Mol. Cell. Biol.* 13: 2942-2951 (1993)). Based on structural differences the receptor-type PTPases may be classified into subtypes (Fischer *et al.*, *Science* 253: 401-406 (1991)): (I) CD45; (II) LAR, PTP $\delta$ , (11) **PTP $\sigma$** ; (III) **PTP**, (12) **SAP-1** (Matozaki *et al.*, *J. Biol. Chem.* 269: 2075-2081 (1994)), (13) **PTP-U2/GLEPP1** (Seimiya *et al.*, *Oncogene* 10: 1731-1738 (1995); Thomas *et al.*, *J. Biol. Chem.* 269: 19953-19962 (1994)), and (14) **DEP-1**; (IV) **PTP $\alpha$** , **PTP $\epsilon$** . All receptor-type PTPases except Type III contain two PTPase domains. Novel PTPases are continuously identified. In the early days of PTPase research, it was believed that the number of PTPs would match that of protein tyrosine kinases (PTKs) (Hanks and Hunter, *FASEB J.* 9: 576-596 (1995)). However, although about 90 open reading frames in *C. elegans* contain the hallmark motif of PTPs, it now seems that the estimate of 'classical' PTPases must be downsized, perhaps to between 100 and 200 in humans.

PTPases are the biological counterparts to protein tyrosine kinases. Therefore, one important function of PTPases is to control, down-regulate, the activity of PTKs. However, a more complex picture of the function of PTPases has emerged. Thus, several studies have shown that some PTPases may actually act as positive mediators of cellular signaling. As an example, the SH2 domain-containing SHP-2 seems to act as a positive mediator in insulin-stimulated Ras activation (Noguchi *et al.*, *Mol. Cell. Biol.* 14: 6674-6682

- (1994)) and of growth factor-induced mitogenic signal transduction (Xiao *et al.*, *J. Biol. Chem.* 269: 21244-21248 (1994)), whereas the homologous SHP-1 seems to act as a negative regulator of growth factor-stimulated proliferation (Bignon and Siminovitch, *Clin. Immunol. Immunopathol.* 73: 168-179 (1994)). Another example of PTPases as
- 5 positive regulators has been provided by studies designed to define the activation of the Src-family of tyrosine kinases. In particular, several lines of evidence indicate that CD45 is positively regulating the activation of hematopoietic cells, possibly through dephosphorylation of the C-terminal tyrosine of Fyn and Lck (Chan *et al.*, *Annu. Rev. Immunol.* 12: 555-592 (1994)).
- 10 PTPases were originally identified and purified from cell and tissue lysates using a variety of artificial substrates and, therefore, their natural function of dephosphorylation was not well known. Since tyrosine phosphorylation by tyrosine kinases is usually associated with cell proliferation, cell transformation and cell differentiation, it was assumed that PTPases were also associated with these events. This association has now been proven to be the
- 15 case with many PTPases. PTP1B, a phosphatase whose structure was the first PTPase to be elucidated (Barford *et al.*, *Science* 263:1397-1404 (1994)) has been shown to be involved in insulin-induced oocyte maturation (Flint *et al.*, *The EMBO J.* 12:1937-46 (1993)) and it has been suggested that the overexpression of this enzyme may be involved in p185<sup>c-erb B2</sup> associated breast and ovarian cancers (Wiener, *et al.*, *J. Natl. cancer Inst.* 86:372-8 (1994);
- 20 Weiner *et al.*, *Am. J. Obstet. Gynecol.* 170:1177-883 (1994)). The association with cancer is recent evidence which suggests that overexpression of PTP1B is statistically correlated with increased levels of p185<sup>c-erb B2</sup> in ovarian and breast cancer. The role of PTP1B in the etiology and progression of the disease has not yet been elucidated. Inhibitors of PTP1B may therefore help clarify the role of PTP1B in cancer and in some cases provide therapeutic treatment
- 25 ment for certain forms of cancer.

#### PTPases: the insulin receptor signaling pathway/diabetes

- 30 Insulin is an important regulator of different metabolic processes and plays a key role in the control of blood glucose. Defects related to its synthesis or signaling lead to diabetes mellitus. Binding of insulin to the insulin receptor (IR) causes rapid (auto)phosphorylation of several tyrosine residues in the intracellular part of the  $\beta$ -subunit. Three closely positioned tyrosine residues (the tyrosine-1150 domain) must all be phosphorylated to obtain full
- 35 activity of the insulin receptor tyrosine kinase (IRTK) which transmits the signal further

downstream by tyrosine phosphorylation of other cellular substrates, including insulin receptor substrate-1 (IRS-1) (Wilden *et al.*, *J. Biol. Chem.* 267: 16660-16668 (1992); Myers and White, *Diabetes* 42: 643-650 (1993); Lee and Pilch, *Am. J. Physiol.* 266: C319-C334 (1994); White *et al.*, *J. Biol. Chem.* 263: 2969-2980 (1988)). The structural basis for the  
5 function of the tyrosine-triplet has been provided by X-ray crystallographic studies of IRTK that showed tyrosine-1150 to be autoinhibitory in its unphosphorylated state (Hubbard *et al.*, *Nature* 372: 746-754 (1994)) and of the activated IRTK (Hubbard, *EMBO J.* 16:5572-5581 (1997)).

Several studies clearly indicate that the activity of the auto-phosphorylated IRTK  
10 can be reversed by dephosphorylation *in vitro* (reviewed in Goldstein, *Receptor* 3: 1-15 (1993); Mooney and Anderson, *J. Biol. Chem.* 264: 6850-6857 (1989)), with the tri-phosphorylated tyrosine-1150 domain being the most sensitive target for protein-tyrosine phosphatases (PTPases) as compared to the di- and mono- phosphorylated forms (King *et al.*, *Biochem. J.* 275: 413-418 (1991)). This tyrosine-triplet functions as a control switch of  
15 IRTK activity and the IRTK appears to be tightly regulated by PTP-mediated dephosphorylation *in vivo* (Khan *et al.*, *J. Biol. Chem.* 264: 12931-12940 (1989); Faure *et al.*, *J. Biol. Chem.* 267: 11215-11221 (1992); Rothenberg *et al.*, *J. Biol. Chem.* 266: 8302-8311 (1991)). The intimate coupling of PTPases to the insulin signaling pathway is further evidenced by the finding that insulin differentially regulates PTPase activity in rat hepatoma  
20 cells (Meyerovitch *et al.*, *Biochemistry* 31: 10338-10344 (1992)) and in livers from alloxan diabetic rats (Boylan *et al.*, *J. Clin. Invest.* 90: 174-179 (1992)).

Until recently, relatively little was known about the identity of the PTPases involved in IRTK regulation. However, the existence of PTPases with activity towards the insulin receptor can be demonstrated as indicated above. Further, when the strong  
25 PTPase-inhibitor pervanadate is added to whole cells an almost full insulin response can be obtained in adipocytes (Fantus *et al.*, *Biochemistry* 28: 8864-8871 (1989); Eriksson *et al.*, *Diabetologia* 39: 235-242 (1995)) and skeletal muscle (Leighton *et al.*, *Biochem. J.* 276: 289-292 (1991)). In addition, other studies show that a new class of peroxovanadium compounds act as potent hypoglycemic compounds *in vivo* (Posner *et al.*, *supra*). Two of  
30 these compounds were demonstrated to be more potent inhibitors of dephosphorylation of the insulin receptor than of the EGF-receptor, thus indicating that even such relatively unselective inhibitors may convey some specificity in regulating different signal transduction pathways.

It was recently found by Montreal-based research groups that mice lacking the protein  
35 tyrosine phosphatase-1B gene (PTP1B) (Elchebly *et al.*, *Science* 283: 1544-1548 (1999))

yielded healthy mice that showed increased insulin sensitivity and resistance to diet-induced obesity. Importantly, these results have been confirmed and extended independently by another research team from Boston (Klaman *et al.*, *Mol. Cell. Biol.* 20: 5479-5489 (2000)). The enhanced insulin sensitivity of the PTP<sup>-/-</sup> mice was also evident in glucose and insulin tolerance tests. The PTP-1B knock-out mouse showed many characteristics which would be highly desirable to have for an anti-diabetes treatment. Most importantly, the knock-out mice grew normally and were fertile and have exhibited no increased incidence of cancer, as obviously there could have been concerns when one considers the mitogenic properties of insulin. From the diabetes perspective, the first notable features of the knock-out animals were that blood glucose and insulin levels were lowered, and the consequent marked increase in insulin sensitivity in the knock-out animals. Moreover, the insulin-stimulated tyrosine phosphorylation levels of IR and IRS-1 were found to be increased/prolonged in muscle and liver - but not in fat tissue. Thus, the main target tissues for this type of approach would appear to be insulin action in liver and muscle. This is in contrast to the main target tissue for the PPAR<sub>γ</sub> agonist class of insulin sensitizers (the "-diones"), which is adipose tissue (Murphy & Nolan, *Exp. Opin. Invest. Drugs* 9: 1347-1361 (2000)). Several other "diabetic" parameters were also improved, such as plasma triglycerides being decreased in the knock-out mice. However, perhaps even more remarkably and unexpectedly, the knock-out animals also exhibited a resistance to weight gain when placed on a high-fat diet. This is again in contrast to the action of the PPAR<sub>γ</sub> agonist class of insulin sensitizers, which rather induce weight gain (Murphy & Nolan, *supra*), and would suggest that inhibition of PTP-1B could be a particularly attractive option for treatment of obese Type II diabetics. This is also supported by the fact that the heterozygous mice from this study showed many of these desirable features. In the Montreal study, there appeared to be no gender differences, whereas in the Boston study in general the male animals had larger responses to PTP-1B being knocked out. In both studies, the reduction in weight gain of the knock-out animals on the high fat diet was found to be due to a decreased fat cell mass, although differences were observed with respect to fat cell number. Leptin levels were also lower in the knock-out mice, presumably as a reflection of the decreased fat mass. Significantly, the Boston group also found that the knock-out animals had an increased energy expenditure of around 20% and an increased respiratory quotient compared to the wild-type; again, heterozygote animals displayed an intermediate level of energy expenditure. Whether this increase in metabolic rate is a reflection of the effects of PTP-1B on insulin-signaling or on other cellular components remains to be established, but the bottom-line message is that inhibition of this enzyme may be an effective anti-diabetic and perhaps also anti-obesity therapy is clear.

It should also be noted that in the PTP-1B knock-out mice the basal tyrosine phosphorylation level of the insulin receptor tyrosine kinase does not appear to be increased, which is in contrast to the situation after insulin treatment where there is an increased or prolonged phosphorylation. This might indicate that other PTPs are controlling the basic phosphorylation state of the insulin receptor in the knock-out mice – and perhaps in man.

Previous findings are in accordance with the results reported by Elchebly *et al.* (supra) (recently reviewed in Kennedy, *Biomed. Pharmacother.* 53: 466-470 (1999)). Thus, it has been found that high glucose concentration induces insulin resistance and increases the expression of PTP1B in rat (fibroblasts expressing the human insulin receptor (Maegawa *et al.*, *J. Biol. Chem.* 270: 7724-7730 (1995)). In rat L6 cells, insulin and insulin-like growth factor I (IGF-I) were found to induce increased PTPase activity, including increased PTP1B expression (Kenner *et al.* *J. Biol. Chem.* 266: 25455-25462 (1993)). In addition, the same group has shown that PTP1B may interact directly with the activated IR (Seely *et al.* *Diabetes* 45: 1379-1385 (1996)) and act directly as a negative regulator of insulin and IGF-I-stimulated signaling (Kenner *et al.* *J. Biol. Chem.* 271: 19810-19816 (1996)). Osmotic loading of rat KRC-7 hepatoma cells with neutralizing anti-PTP1B antibodies also indicated a role for PTP1B in negative regulating of the insulin signaling pathway (Akmad *et al.* *J. Biol. Chem.* 270: 20503-20508 (1995)).

Also other PTPases have been implicated as regulators of the insulin signaling pathway. Thus, it was found that the ubiquitously expressed SH2 domain containing PTPase, PTP1D/SHP-2 (Vogel *et al.*, 1993, *supra*), associates with and dephosphorylates IRS-1, but apparently not the IR itself (Kuhné *et al.*, *J. Biol. Chem.* 268: 11479-11481 (1993); (Kuhné *et al.*, *J. Biol. Chem.* 269: 15833-15837 (1994)).

Other studies suggest that receptor-type or membrane-associated PTPases are involved in IRTK regulation (Faure *et al.*, *J. Biol. Chem.* 267: 11215-11221 (1992), (Häring *et al.*, *Biochemistry* 23: 3298-3306 (1984); Sale, *Adv. Prot. Phosphatases* 6: 159-186 (1991)). Hashimoto *et al.* have proposed that LAR might play a role in the physiological regulation of insulin receptors in intact cells (Hashimoto *et al.*, *J. Biol. Chem.* 267: 13811-13814 (1992)). Their conclusion was reached by comparing the rate of dephosphorylation/inactivation of purified IR using recombinant PTP1B as well as the cytoplasmic domains of LAR and PTP $\alpha$ . Antisense inhibition was used to study the effect of LAR on insulin signaling in a rat hepatoma cell line (Kulas *et al.*, *J. Biol. Chem.* 270: 2435-2438 (1995)). A suppression of LAR protein levels by about 60 percent was paralleled by an approximately 150 percent increase in insulin-induced auto-phosphorylation. However, only

a modest 35 percent increase in IRTK activity was observed, whereas the insulin-dependent phosphatidylinositol 3-kinase (PI 3-kinase) activity was significantly increased by 350 percent. Reduced LAR levels did not alter the basal level of IRTK tyrosine phosphorylation or activity. The authors speculate that LAR could specifically  
5 dephosphorylate tyrosine residues that are critical for PI 3-kinase activation either on the insulin receptor itself or on a downstream substrate. Conflicting results have been reported for PTP-LAR knock-out mice. Thus, Goldstein and coworkers reported that transgenic mice deficient in PTP-LAR exhibit profound defects in glucose-homeostasis (Ren *et al.*, *Diabetes* 47: 493-497 (1998)). However, it is difficult to fully assess the  
10 contribution of LAR deficiency to the glucose homeostasis in these mice due to the fact that the control mice were of a different genetic background than the knock-out mice. Moreover, normal glucose homeostasis was reported in a different strain of PTP-LAR knock-out mice (Sorensen *et al.*, *Diabetologia* 40: A143 (1997)).

While previous reports indicate a role of PTP $\alpha$  in signal transduction through src  
15 activation (Zheng *et al.*, *Nature* 359: 336-339 (1992); den Hertog *et al.*, *EMBO J.* 12: 3789-3798 (1993)) and interaction with GRB-2 (den Hertog *et al.*, *EMBO J.* 13: 3020-3032 (1994); Su *et al.*, *J. Biol. Chem.* 269: 18731-18734 (1994)), Møller, Lammers and coworkers provided results that suggest a function for this phosphatase and its close relative PTP  $\beta$  as negative regulators of the insulin receptor signal (Møller *et al.*, 1995  
20 *supra*; Lammers, *et al.*, *FEBS Lett.* 404:37-40 (1997)). These studies also indicated that receptor-like PTPases might play a significant role in regulating the IRTK.

Other studies have shown that PTP1B and TC-PTP are likely to be involved in the regulation of several other cellular processes in addition to the described regulatory roles in  
25 insulin signaling. Therefore, PTP1B and/or TC-PTP as well as other PTPases showing key structural features with PTP1B and TC-PTP are likely to be important therapeutic targets in a variety of human and animal diseases. The compounds of the present invention are useful for modulating or inhibiting PTP1B and/or TC-PTP and/or other PTPases showing key structural features with said PTPases and for treating diseases in which said  
30 modulation or inhibition is indicated. A few examples that are not intended in any way to limit the scope of the invention of substrates that may be regulated by PTP1B will be given below.

Tonks and coworkers have developed an elegant 'substrate trapping' technique that has allowed identification of the epidermal growth factor receptor (EGF-R) as a major  
35 substrate of PTP1B in COS cells (Flint *et al.*, *Proc. Natl. Acad. Sci. USA* 94: 1680-1685

(1997)). In addition, three other as yet unidentified substrates of PTP1B were isolated. As an example of these studies, it has been found - using the above substrate-trapping technique - that PTP1B in addition to the EGF-R associates with activated platelet-derived growth factor receptor (PDGF-R), but not with colony-stimulating factor 1 receptor (CSF-1R) (Liu & Chernoff, *Biochem. J.* 327: 139-145 (1997)).

Early studies have shown that the subcellular localization as well as the enzyme activity of PTP1B may be regulated by agonist-induced calpain-catalyzed cleavage in human platelets (Frangioni *et al. EMBO J.* 12: 4843-4856 (1993)). Moreover, PTP1B cleavage correlated with the transition from reversible to irreversible platelet aggregation. Thus, as a non-limiting example compounds of the present invention might be used to prevent or induce irreversible platelet aggregation in individuals in need thereof. It was proposed that the cleavage-induced change in the subcellular localization of PTP1B (from membrane to cytosol) results in different substrate specificity not only in platelet but also in other cell types (Frangioni *et al.*, *supra*).

The above substrate trapping method has further been used to identify the protein tyrosine kinase p210<sup>bcr-abl</sup> as a substrate for PTP1B (LaMontagne, Jr. *et al. Mol. Cell. Biol.* 18: 2965-2975 (1998)). These studies suggest that PTP1B might function as a negative regulator of p210<sup>bcr-abl</sup> signaling *in vivo*. In addition, PTP1B was recently found to bind to and dephosphorylate the docking protein p130<sup>Cas</sup> in rat fibroblasts and thereby suppress transformation by v-crk, v-src, and v-ras, but not by v-raf (Liu *et al. Mol. Cell. Biol.* 18: 250-259 (1998)).

The transmembrane PTPase CD45, which is believed to be hematopoietic cell-specific, was found to negatively regulate the insulin receptor tyrosine kinase in the human multiple myeloma cell line U266 (Kulas *et al., J. Biol. Chem.* 271: 755-760 (1996)).

Further, PTPases influences the following hormones or diseases or disease states: somatostatin, the immune system/autoimmunity, cell-cell interactions/cancer, platelet aggregation, osteoporosis, and microorganisms, as disclosed in PCT Publication WO 99/15529.

Somatostatin inhibits several biological functions including cellular proliferation (Lamberts *et al., Molec. Endocrinol.* 8: 1289-1297 (1994)). While part of the antiproliferative activities of somatostatin are secondary to its inhibition of hormone and growth factor secretion (e.g. growth hormone and epidermal growth factor), other antiproliferative effects of somatostatin are due to a direct effect on the target cells. As an example, somatostatin analogs inhibit the growth of pancreatic cancer presumably via stimulation of a single PTPase, or a subset of PTPases, rather than a general activation of PTPase levels in the

cells (Liebow *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 2003-2007 (1989); Colas *et al.*, *Eur. J. Biochem.* 207: 1017-1024 (1992)).

PTPases: the immune system/autoimmunity

Several studies suggest that the receptor-type PTPase CD45 plays a critical role not only for initiation of T cell activation, but also for maintaining the T cell receptor-mediated signaling cascade. These studies are reviewed in: (Weiss A., *Ann. Rev. Genet.* 25: 487-510 (1991); Chan *et al.*, *Annu. Rev. Immunol.* 12: 555-592 (1994); Trowbridge and Thomas, *Annu. Rev. Immunol.* 12: 85-116 (1994)).

10

CD45 is one of the most abundant of the cell surface glycoproteins and is expressed exclusively on hemopoietic cells. In T cells, it has been shown that CD45 is one of the critical components of the signal transduction machinery of lymphocytes. In particular, evidence has suggested that CD45 phosphatase plays a pivotal role in antigen-stimulated proliferation of T lymphocytes after an antigen has bound to the T cell receptor (Trowbridge, *Ann. Rev. Immunol.*, 12: 85-116 (1994)). Several studies suggest that the PTPase activity of CD45 plays a role in the activation of Lck, a lymphocyte-specific member of the Src family protein-tyrosine kinase (Mustelin *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 6302-6306 (1989); Ostergaard *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 8959-8963 (1989)). These authors hypothesized that the phosphatase activity of CD45 activates Lck by dephosphorylation of a C-terminal tyrosine residue, which may, in turn, be related to T-cell activation. Thus, it was found that recombinant p56lck specifically associates with recombinant CD45 cytoplasmic domain protein, but not to the cytoplasmic domain of the related PTP $\alpha$  (Ng *et al.*, *J. Biol. Chem.* 271: 1295-1300 (1996)). The p56lck-CD45 interaction seems to be mediated via a nonconventional SH2 domain interaction not requiring phosphotyrosine. In immature B cells, another member of the Src family protein-tyrosine kinases, Fyn, seems to be a selective substrate for CD45 compared to Lck and Syk (Katagiri *et al.*, *J. Biol. Chem.* 270: 27987-27990 (1995)).

15

20

25

Studies using transgenic mice with a mutation for the CD45-exon6 exhibited lacked mature T cells. These mice did not respond to an antigenic challenge with the typical T cell mediated response (Kishihara *et al.*, *Cell* 74:143-56 (1993)). Inhibitors of CD45 phosphatase would therefore be very effective therapeutic agents in conditions that are associated with autoimmune diseases with rheumatoid arthritis, systemic lupus erythematosus, type I diabetes, and inflammatory bowel disease as non-limiting examples. Another important use of CD45 inhibitors is for immunosuppression in connection with tissue or cell transplantation and other conditions with need for immunosuppressive treatment.

30

35

CD45 has also been shown to be essential for the antibody mediated d granulation of mast cells (Berger *et al.*, *J. Exp. Med.* 180:471-6 (1994)). These studies were also done with mice that were CD45-deficient. In this case, an IgE-mediated degranulation was demonstrated in wild type but not CD45-deficient T cells from mice. These data suggest that CD45 inhibitors could also play a role in the symptomatic or therapeutic treatment of allergic disorders with asthma, allergic rhinitis, food allergy, eczema, urticaria and anaphylaxis as non-limiting examples.

Another PTPase, an inducible lymphoid-specific protein tyrosine phosphatase (HePTP) has also been implicated in the immune response. This phosphatase is expressed in both resting T and B lymphocytes, but not non-hemopoietic cells. Upon stimulation of these cells, mRNA levels from the HePTP gene increase 10-15 fold (Zanke *et al.*, *Eur. J. Immunol.* 22: 235-239 (1992)). In both T and B cells HePTP may function during sustained stimulation to modulate the immune response through dephosphorylation of specific residues. Its exact role, however remains to be defined.

Likewise, the hematopoietic cell specific SHP-1 seems to act as a negative regulator and play an essential role in immune cell development. In accordance with the above-mentioned important function of CD45, HePTP and SHP-1, selective PTPase inhibitors may be attractive drug candidates both as immunosuppressors and as immunostimulants. Recent studies illustrate the potential of PTPase inhibitors as immunomodulators by demonstrating the capacity of the non-selective vanadium-based PTPase inhibitor, BMLOV, to induce apparent B cell selective apoptosis compared to T cells (Dawson *et al.*, *FEBS Lett.* 478: 233-236; Schieven *et al.*, *J. Biol. Chem.* 270: 20824-20831 (1995)).

#### PTPases: cell-cell interactions/cancer

Focal adhesion plaques, an *in vitro* phenomenon in which specific contact points are formed when fibroblasts grow on appropriate substrates, seem to mimic, at least in part, cells and their natural surroundings. Several focal adhesion proteins are phosphorylated on tyrosine residues when fibroblasts adhere to and spread on extracellular matrix (Gumbiner, *Neuron* 11: 551-564 (1993)). However, aberrant tyrosine phosphorylation of these proteins can lead to cellular transformation. The intimate association between PTPases and focal adhesions is supported by the finding of several intracellular PTPases with ezrin-like N-terminal domains, e.g. PTPMEG1 (Gu *et al.*, *Proc. Natl. Acad. Sci. USA* 88: 5867-5871 (1991), PTPH1 (Yang and Tonks, *Proc. Natl. Acad. Sci. USA* 88: 5949-5953 (1991)) and PTPD1 (Møller *et al.*, *Proc. Natl. Acad. Sci. USA* 91: 7477-7481 (1994)). The ezrin-like domain shows similarity to several proteins that are

believed to act as links between the cell membrane and the cytoskeleton. PTPD1 was found to be phosphorylated by and associated with c-src *in vitro* and is hypothesized to be involved in the regulation of phosphorylation of focal adhesions (Møller *et al.*, *supra*).

PTPases may oppose the action of tyrosine kinases, including those responsible  
5 for phosphorylation of focal adhesion proteins, and may therefore function as natural inhibitors of transformation. TC-PTP, and especially the truncated form of this enzyme (Cool *et al.*, *Proc. Natl. Acad. Sci. USA* 87: 7280-7284 (1990)), can inhibit the transforming activity of v-erb and v-fms (Lammers *et al.*, *J. Biol. Chem.* 268: 22456-22462 (1993), Zander *et al.*, *Oncogene* 8: 1175-1182 (1993)). Moreover, it was found that transformation  
10 by the oncogenic form of the *HER2/neu* gene was suppressed in NIH 3T3 fibroblasts overexpressing PTP1B (Brown-Shimer *et al.*, *Cancer Res.* 52: 478-482 (1992)).

The expression level of PTP1B was found to be increased in a mammary cell line transformed with *neu* (Zhay *et al.*, *Cancer Res.* 53: 2272-2278 (1993)). The intimate relationship between tyrosine kinases and PTPases in the development of cancer is further  
15 evidenced by the finding that PTP $\epsilon$  is highly expressed in murine mammary tumors in transgenic mice over-expressing c-*neu* and v-Ha-*ras*, but not c-*myc* or *int-2* (Elson and Leder, *J. Biol. Chem.* 270: 26116-26122 (1995)). Further, the human gene encoding PTP $\gamma$  was mapped to 3p21, a chromosomal region, which is frequently deleted in renal and lung carcinomas (LaForgia *et al.*, *Proc. Natl. Acad. Sci. USA* 88: 5036-5040 (1991)).

20 In this context, it seems significant that PTPases appear to be involved in controlling the growth of fibroblasts. Thus, it was found that Swiss 3T3 cells harvested at high density contain a membrane-associated PTPase whose activity on an average is 8-fold higher than that of cells harvested at low or medium density (Pallen and Tong, *Proc. Natl. Acad. Sci. USA* 88: 6996-7000 (1991)). It was hypothesized by the authors that  
25 density-dependent inhibition of cell growth involves the regulated elevation of the activity of the PTPase(s) in question. In accordance with this view, a membrane-bound, receptor-type PTPase, DEP-1, showed enhanced ( $\geq 10$ -fold) expression levels with increasing cell density of WI-38 human embryonic lung fibroblasts and in the AG1518 fibroblast cell line (Östman *et al.*, *Proc. Natl. Acad. Sci. USA* 91: 9680-9684 (1994)).

30 Two closely related receptor-type PTPases, PTP $\alpha$  and PTP $\mu$ , can mediate homophilic cell-cell interaction when expressed in non-adherent insect cells, suggesting that these PTPases might have a normal physiological function in cell-to-cell signalling (Gebbinck *et al.*, *J. Biol. Chem.* 268: 16101-16104 (1993), Brady-Kalnay *et al.*, *J. Cell Biol.* 122: 961-972 (1993); Sap *et al.*, *Mol. Cell. Biol.* 14: 1-9 (1994)). Interestingly, PTP $\alpha$  and  
35 PTP $\mu$  do not interact with each other, despite their structural similarity (Zondag *et al.*, *J.*

*Biol. Chem.* 270: 14247-14250 (1995)). From the studies described above it is apparent that PTPases may play an important role in regulating normal cell growth. However, as pointed out above, other studies indicate that PTPases may also function as positive mediators of intracellular signaling and thereby induce or enhance mitogenic responses.

- 5 Increased activity of certain PTPases might therefore result in cellular transformation and tumor formation. Indeed, in one study over-expression of PTP $\alpha$  was found to lead to transformation of rat embryo fibroblasts (Zheng, *supra*). In addition, SAP-1 was found to be highly expressed in pancreatic and colorectal cancer cells. SAP-1 is mapped to chromosome 19 region q13.4 and might be related to carcinoembryonic antigen mapped to  
10 19q13.2 (Uchida *et al.*, *J. Biol. Chem.* 269: 12220-12228 (1994)). Further, the dsPTPase, cdc25, dephosphorylates cdc2 at Thr14/Tyr-15 and thereby functions as positive regulator of mitosis (reviewed by Hunter, *Cell* 80: 225-236 (1995)). Inhibitors of specific PTPases are therefore likely to be of significant therapeutic value in the treatment of certain forms of cancer.

15

#### PTPases: platelet aggregation

- PTPases seem to be centrally involved in platelet aggregation. Thus, agonist-induced platelet activation results in calpain-catalyzed cleavage of PTP1B with a concomitant 2-fold  
20 stimulation of PTPase activity (Frangioni *et al.*, *EMBO J.* 12: 4843-4856 (1993)). The cleavage of PTP1B leads to subcellular relocation of the enzyme and correlates with the transition from reversible to irreversible platelet aggregation in platelet-rich plasma. In addition, the SH2 domain containing PTPase, SHP-1, was found to translocate to the cytoskeleton in platelets after thrombin stimulation in an aggregation-dependent manner (Li  
25 *et al.*, *FEBS Lett.* 343: 89-93 (1994)).

- Although some details in the above two studies have been questioned, there is over-all agreement that PTP1B and SHP-1 play significant functional roles in platelet aggregation (Ezumi *et al.*, *J. Biol. Chem.* 270: 11927-11934 (1995)). In accordance with these observations, treatment of platelets with the PTPase inhibitor pervanadate leads to  
30 significant increase in tyrosine phosphorylation, secretion and aggregation (Pumiglia *et al.*, *Biochem. J.* 286: 441-449 (1992)).

PTPases: osteoporosis

The rate of bone formation is determined by the number and the activity of osteoblasts, which in turn are determined by the rate of proliferation and differentiation of osteoblast progenitor cells, respectively. Histomorphometric studies indicate that the osteoblast number is the primary determinant of the rate of bone formation in humans (Gruber *et al.*, *Mineral Electrolyte Metab.* 12: 246-254 (1987), reviewed in Lau *et al.*, *Biochem. J.* 257: 23-36 (1989)). Acid phosphatases/PTPases may be involved in negative regulation of osteoblast proliferation. Thus, fluoride, which has phosphatase inhibitory activity, has been found to increase spinal bone density in osteoporotics by increasing osteoblast proliferation (Lau *et al.*, *supra*). Consistent with this observation, an osteoblastic acid phosphatase with PTPase activity was found to be highly sensitive to mitogenic concentrations of fluoride (Lau *et al.*, *J. Biol. Chem.* 260: 4653-4660 (1985), Lau *et al.*, *J. Biol. Chem.* 262: 1389-1397 (1987), Lau *et al.*, *Adv. Protein Phosphatases* 4: 165-198 (1987)). Interestingly, the level of membrane-bound PTPase activity was increased dramatically when the osteoblast-like cell line UMR 106.06 was grown on collagen type-I matrix compared to uncoated tissue culture plates. Since a significant increase in PTPase activity was observed in density-dependent growth arrested fibroblasts (Pallen and Tong, *Proc. Natl. Acad. Sci.* 88: 6996-7000 (1991)), it might be speculated that the increased PTPase activity directly inhibits cell growth. The mitogenic action of fluoride and other phosphatase inhibitors (molybdate and vanadate) may thus be explained by their inhibition of acid phosphatases/PTPases that negatively regulate the cell proliferation of osteoblasts. The complex nature of the involvement of PTPases in bone formation is further suggested by the identification of a novel parathyroid regulated, receptor-like PTPase, OST-PTP, expressed in bone and testis (Mauro *et al.*, *J. Biol. Chem.* 269: 30659-30667 (1994)). OST-PTP is up-regulated following differentiation and matrix formation of primary osteoblasts and subsequently down-regulated in the osteoblasts which are actively mineralizing bone in culture. It may be hypothesized that PTPase inhibitors may prevent differentiation via inhibition of OST-PTP or other PTPases thereby leading to continued proliferation. This would be in agreement with the above-mentioned effects of fluoride and the observation that the tyrosine phosphatase inhibitor orthovanadate appears to enhance osteoblast proliferation and matrix formation (Lau *et al.*, *Endocrinology* 116: 2463-2468 (1988)). In addition, it was observed that vanadate, vanadyl and pervanadate all increased the growth of the osteoblast-like cell line UMR106. Vanadyl and pervanadate were stronger stimulators of cell growth than vanadate. Only vanadate was able to regulate the cell differentiation as measured by cell alkaline phosphatase

activity (Cortizo *et al.*, *Mol. Cell. Biochem.* 145: 97-102 (1995)). It is of particular interest to the current invention that several studies have shown that bisphosphonates, such as alendronate and tiludronate, inhibit the PTPase activity in osteoclasts, and that the inhibition of PTPase activity correlated with the inhibition of *in vitro* osteoclast formation and boneresorption (Schmidt *et al.*, *Proc. Natl. Acad. Sci. U.S.A.* 93: 3068-3073 (1996); Murakami *et al.*, *Bone* 20: 399-404 (1997); Opas *et al.*, *Biochem. Pharmacol.* 54: 721-727 (1997); Skorey *et al.*, *J. Biol. Chem.* 272: 22472-22480 (1997)). Thus, PTPase inhibitors – other than bisphosphonates – can potentially be effective for prevention and/or treatment of osteoporosis.

#### PTPases: microorganisms

Dixon and coworkers have called attention to the fact that PTPases may be a key element in the pathogenic properties of *Yersinia* (reviewed in Clemens *et al. Molecular Microbiology* 5: 2617-2620 (1991)). This finding was rather surprising since tyrosine phosphate is thought to be absent in bacteria. The genus *Yersinia* comprises 3 species: *Y. pestis* (responsible for the bubonic plague), *Y. pseudotuberculosis* and *Y. enterocolitica* (causing enteritis and mesenteric lymphadenitis). Interestingly, a dual-specificity phosphatase, VH1, has been identified in Vaccinia virus (Guan *et al.*, *Nature* 350: 359-263 (1991)). These observations indicate that PTPases may play critical roles in microbial and parasitic infections, and they further point to PTPase inhibitors as a novel, putative treatment principle of infectious diseases.

WO 99/46267 discloses compounds, which are pharmacologically useful inhibitors of PTPases. However, the present invention, which represents a novel selection under WO 99/46267, discloses a class of compounds which surprisingly are more potent against protein tyrosine phosphatases (e.g. PTP1B) than those disclosed in WO 99/46267.

The compounds of the invention can be further modified to act as prodrugs.

It is a well known problem in drug discovery that compounds, such as enzyme inhibitors, may be very potent and selective in biochemical assays, yet be inactive in vivo. This lack of so-called bioavailability may be ascribed to a number of different factors such as lack of or poor absorption in the gut, first pass metabolism in the liver, poor uptake in cells. Although the factors determining bioavailability are not completely understood, there are many examples in the scientific literature - well known to those skilled in the art - of how to modify

compounds, which are potent and selective in biochemical assays but show low or no activity in vivo, into drugs that are biologically active. It is within the scope of the invention to modify the compounds of the invention, termed the 'original compound', by attaching chemical groups that will improve the bioavailability of said compounds in such a way that the uptake

5 in cells or mammals is facilitated. Examples of said modifications, which are not intended in any way to limit the scope of the invention, include changing of one or more carboxy groups to esters (for instance methyl esters, ethyl esters, acetoxymethyl esters or other acyloxy-methyl esters). Compounds of the invention, original compounds, such modified by attaching chemical groups are termed 'modified compounds'. Said chemical groups may or may not be

10 apparent in the claims of this invention. Other examples of modified compounds, which are not intended in any way to limit the scope of the invention, are compounds that have been cyclized at specific positions - so-called 'cyclic compounds' - which upon uptake in cells or mammals become hydrolyzed at the same specific position(s) in the molecule to yield the compounds of the invention, the original compounds, which are then said to be 'non-cyclic'.

15 For the avoidance of doubt, it is understood that the latter original compounds in most cases will contain other cyclic or heterocyclic structures that will not be hydrolyzed after uptake in cells or mammals. Generally, said modified compounds will not show a behavior in biochemical assays similar to that of the original compound, i.e. the corresponding compounds of the invention without the attached chemical groups or said modifications. Said modified

20 compounds may even be inactive in biochemical assays. However, after uptake in cells or mammals these attached chemical groups of the modified compounds may in turn be removed spontaneously or by endogenous enzymes or enzyme systems to yield compounds of the invention, original compounds. 'Uptake' is defined as any process that will lead to a substantial concentration of the compound inside cells or in mammals. After uptake in cells or

25 mammals and after removal of said attached chemical group or hydrolysis of said cyclic compound, the compounds may have the same structure as the original compounds and thereby regain their activity and hence become active in cells and/or in vivo after uptake. A number of procedures, well known to those skilled in the art, may be used to verify that the attached chemical groups have been removed or that the cyclic compound has been hydro-

30 lyzed after uptake in cells or mammals. An example, which is not intended in any way to limit the scope of the invention, is given in the following. A mammalian cell line, which can be obtained from the American Tissue Type Collection or other similar governmental or commercial sources, is incubated with said modified compound. After incubation at conditions well known to those skilled in the art, the cells are washed appropriately, lysed and the lysate is

35 isolated. Appropriate controls, well known to those skilled in the art, must be included. A

number of different procedures, well known to those skilled in the art, may in turn be used to extract and purify said compound from said lysate. Said compound may or may not retain the attached chemical group or said cyclic compound may or may not have been hydrolyzed. Similarly, a number of different procedures - well known to those skilled in the art - may be used to structurally and chemically characterize said purified compound. Since said purified compound has been isolated from said cell lysate and hence has been taken up by said cell line, a comparison of said structurally and chemically characterized compound with that of the original unmodified compound (i.e. without said attached chemical group or said non-cyclic compound) will immediately provide those skilled in the art information on whether the attached chemical group has been removed in the cell or if the cyclic compound has been hydrolyzed. As a further analysis, said purified compound may be subjected to enzyme kinetic analysis as described in detail in the present invention. If the kinetic profile is similar to that of the original compound without said attached chemical group, but different from said modified compound, this confirms that said chemical group has been removed or said cyclic compounds has been hydrolyzed. Similar techniques may be used to analyze compounds of the invention in whole animals and mammals.

A preferred prodrug is acetoxymethyl esters of the compounds of the present invention which may be prepared by the following general procedure (*C. Schultz et al, The Journal of Biological Chemistry, 1993, 268, 6316-6322.*):

A carboxylic acid (1 equivalent) is suspended in dry acetonitrile (2 ml per 0.1 mmol). Diisopropyl amine (3.0 equivalents) is added followed by bromomethyl acetate (1.5 equivalents). The mixture is stirred under nitrogen overnight at room temperature. Acetonitrile is removed under reduced pressure to yield an oil which is diluted in ethyl acetate and washed with water (3 x). The organic layer is dried over anhydrous magnesium sulfate. Filtration followed by solvent removal under reduced pressure afford a crude oil. The product is purified by column chromatography on silica gel, using an appropriate solvent system.

## PHARMACOLOGICAL METHODS

The compounds are evaluated for biological activity with a truncated form of PTP1B (corresponding to the first 321 amino acids), which was expressed in *E. coli* and purified to apparent homogeneity using published procedures well-known to those skilled in the art. The enzyme reactions are carried out using standard conditions essentially as described by Burk et al. (*Biochemistry* 35; 15989-15996 (1996)). The assay conditions are as follows. Appropriate concentrations of the compounds of the invention are added to the reaction mixtures containing different concentrations of the substrate, *p*-nitrophenyl phosphate (range: 0.16 to 10 mM - final assay concentration). The buffer used was 50 mM HEPES pH 7.0, 100 mM sodium chloride, 0.1 % (w/v) bovine serum albumin, 5 mM glutathione, and 1 mM EDTA. ). The reaction was started by addition of the enzyme and carried out in microtiter plates at 25° C for 60 minutes. The reactions are stopped by addition of NaOH. The enzyme activity was determined by measurement of the absorbance at 405 nm with appropriate corrections for

**Analysis for blood glucose lowering effects**

The compounds of the invention are tested for blood glucose lowering effects in diabetic, obese female *ob/ob* mice. The mice are of similar age and body weights and they are randomized into groups of ten mice. They have free access to food and water during the experiment. The compounds are administered by either by gavage, subcutaneous, intravenous or intraperitoneal injections. The control group receives the same volume of vehicle as the mice that receive the compounds. Non-limiting examples of dose-range: 0.1, 0.3, 1.0, 3.0, 10, 30, 100 mg per kg body weight. The blood glucose levels are measured two times before administration of the compounds of the invention and vehicle (to the control group). After administration of the compound, the blood glucose levels are measured at the following time points: 1, 2, 4, 6, and 8 hours. A positive response is defined either as (i) a more than 25 percent reduction in blood glucose levels in the group receiving the compound of the invention com-

par d to the group receiving the vehicle at any time point or (ii) statistically significant (i.e.  $p < 0.05$ ) reduction in the area under the blood glucose curve during the whole period (i.e. 8 hrs) in the group treated with the compounds of the invention compared to the group receiving the vehicle.

- 5 Compounds that show positive response can be used as development candidates and used for treatment of human diseases such as diabetes and obesity.

An additional portion of imidazol-1-yl-oxo-acetic acid *tert* butyl ester (0.3 g, 1.6 mmol) in tetrahydrofuran (2 ml) was added. The reaction mixture was allowed to stir at room temperature for an additional 60 hours. The reaction mixture was poured into water (50 ml) and extracted with ethyl acetate (3 x 50 ml). The combined organic phases were washed with brine (3 x 50 ml) dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and the organic phase evaporated in vacuo. The residue (0.5 g) was purified by column chromatography (300 ml silicagel) using a mixture of ethyl acetate/heptane (1:2) as eluent. Pure fractions were collected and the solvent evaporated in vacuo affording 0.36 g (80 %) of 2-(*tert*-butoxyoxalyl-amino)-5-(4-chloro-1,3-dioxo-1,3-dihydro-isoindol-2-ylmethyl)-4,7-dihydro-5*H*-thieno[2,3-*c*]pyran-3-carboxylic acid *tert*-butyl ester as a solid.

To a solution of 4-hydroxyphthalic acid (0.25 g, 1.37 mmol) in anhydrous N,N-dimethylformamide (3 ml) under nitrogen was added sodium hydride (0.22 g, 5.48 mmol). The solution was stirred for 5 minutes and then methyl iodide (0.68 ml) was added and continued stirring for 3 hours. Several drops of water were added to quench the reaction and the mixture was concentrated in vacuo. The crude material was partitioned between ethyl acetate (40 ml) and water (10 ml). The layers were separated and the organic layer washed with brine (2 x 10 ml), dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and the solvent evaporated in vacuo. 1. ☒ Claims Nos.: **81, 85-86, 93, 96, 99**  
because they relate to subject matter not required to be searched by this Authority, namely:  
**see next sheet**
2. ☒ Claims Nos.: **89**  
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:  
**see next sheet**
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box II** Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
